Probability Distributions

Data can be "distributed" (spread out) in different ways.

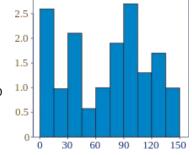

It can be spread out more on the left

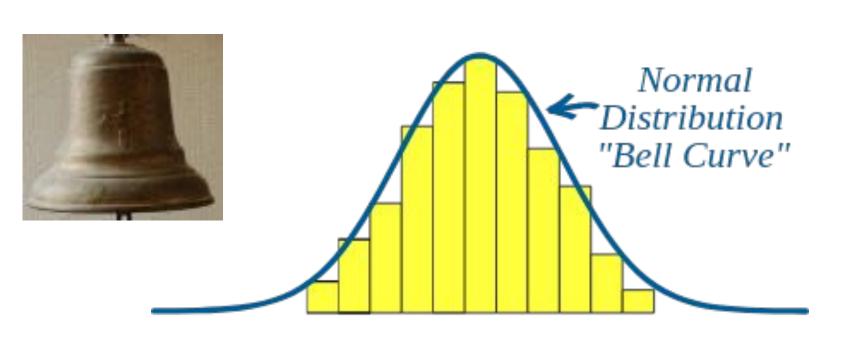

Or more on the right

Or it can be all jumbled up

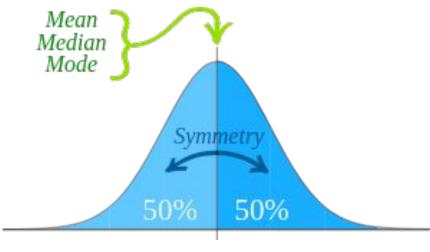

Many things closely follow a Normal Distribution:

- heights of people
- size of things produced by machines
- errors in measurements
- blood pressure
- marks on a test

We say the data is "normally distributed":

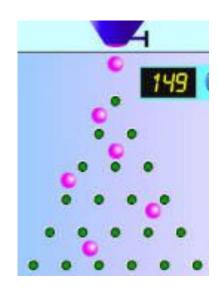

The Normal Distribution has:

- mean = median = mode
- symmetry about the centre
- 50% of values less than the mean and 50% greater than the mean

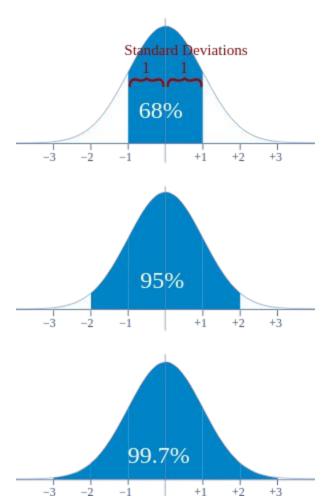

#### Quincunx

Quincunx

#### **Standard Deviations**

The <u>Standard Deviation</u> is a measure of how spread out numbers are (read that page for details on how to calculate it).

68% of values are within 1 standard deviation of the mean

95% of values are within 2 standard deviations of the mean

99.7% of values are within 3 standard deviations of the mean

Example: 95% of students at school are between 1.1m and 1.7m tall.

Assuming this data is normally distributed can you calculate the mean and standard deviation?

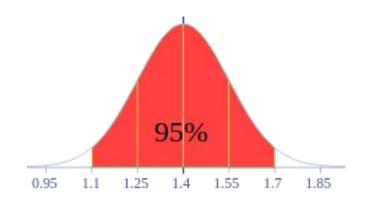

The mean is halfway between 1.1m and 1.7m:

Mean = 
$$(1.1m + 1.7m) / 2 = 1.4m$$

95% is 2 standard deviations either side of the mean (a total of 4 standard deviations) so:

1 standard deviation = 
$$(1.7m-1.1m)/4$$

- = 0.6m / 4
- = 0.15m

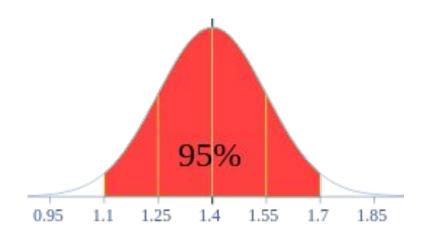

#### **Standard Scores**

The number of standard deviations from the mean is also called the "Standard Score", "sigma" or "z-score". Get used to those words!

# Example: In that same school one of your friends is 1.85m tall

You can see on the bell curve that 1.85m is 3 standard deviations from the mean of 1.4, so:

Your friend's height has a "z-score" of 3.0

It is also possible to calculate how many standard deviations 1.85 is from the mean

How far is 1.85 from the mean?

It is 1.85 - 1.4 = 0.45m from the mean

How many standard deviations is that? The standard deviation is 0.15m, so:

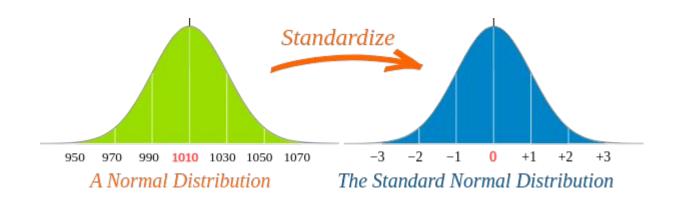

0.45 m / 0.15 m = 3 standard deviations

So to convert a value to a Standard Score ("z-score"):

first subtract the mean,

then divide by the Standard Deviation

# And doing that is called "Standardizing":

### Example: Travel Time

A survey of daily travel time had these results (in minutes):

26, 33, 65, 28, 34, 55, 25, 44, 50, 36, 26, 37, 43, 62, 35, 38, 45, 32, 28, 34

The Mean is 38.8 minutes, and the Standard Deviation is 11.4 minutes (you can copy and paste the values into the Standard Deviation Calculator if you want).

oopy and paste the values into the standard beviation salediate in you want).

Convert the values to z-scores ("standard scores").

#### To convert 26:

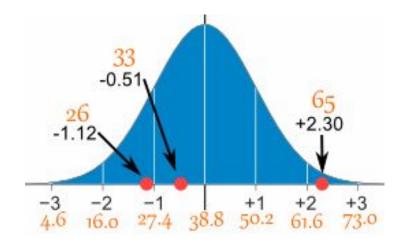

- first subtract the mean: 26 38.8 = -12.8,
- then divide by the Standard Deviation: -12.8/11.4 = -1.12

So 26 is -1.12 Standard Deviations from the Mean

#### Here are the first three conversions

Original Value	Calculation	Standard Score (z-score)
26	(26-38.8) / 11.4 =	-1.12
33	(33-38.8) / 11.4 =	-0.51
65	(65-38.8) / 11.4 =	+2.30

### And here they are graphically:

You can calculate the rest of the z-scores yourself!

# The z-score formula that we have been using is:

$$z = \frac{x - \mu}{\sigma}$$

- z is the "z-score" (Standard Score)
- x is the value to be standardised
- μ ('mu") is the mean
- σ ("sigma") is the standard deviation

# Why Standardize ... ?

It can help us make decisions about our data.

### Example: Professor Willoughby is marking a test.

Here are the students' results (out of 60 points):

Most students didn't even get 30 out of 60, and most will fail.

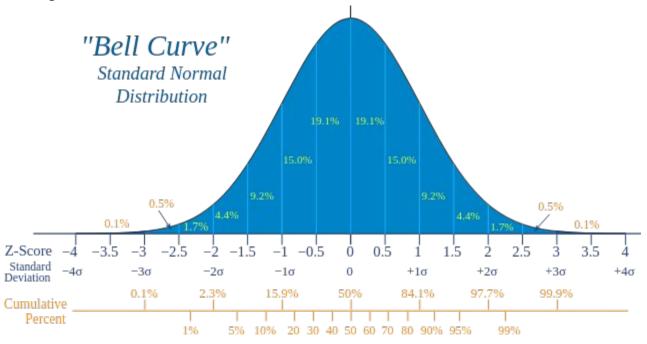

The test must have been really hard, so the Prof decides to Standardize all the scores and only fail people more than 1 standard deviation below the mean.

The Mean is 23, and the Standard Deviation is 6.6, and these are the Standard Scores:

Now only 2 students will [a] (the ones lower than -1 standard deviation)

Much fairer!

Here is the Standard Normal Distribution with percentages for every half of a standard deviation, and cumulative percentages:

Example: Your score in a recent test was 0.5 standard deviations above the average, how many people scored lower than you did?

Between 0 and 0.5 is 19.1%

Less than 0 is 50% (left half of the curve)

So the total less than you is:

50% + 19.1% = 69.1%

In theory 69.1% scored less than you did (but with real data the percentage may be different)

#### A Practical Example: Your company packages sugar in 1 kg bags.

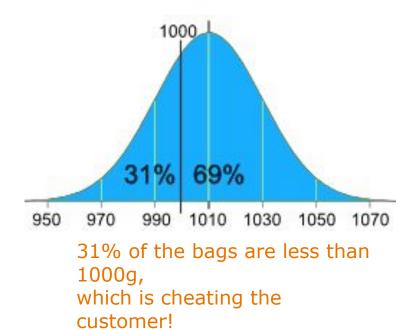

When you weigh a sample of bags you get these results:

- 1007g, 1032g, 1002g, 983g, 1004g, ... (a hundred measurements)
- Mean = 1010g
- Standard Deviation = 20g

Some values are less than 1000g ... can you fix that?

The normal distribution of your measurements looks like this:

It is a random thing, so we can't stop bags having less than 1000g, but we can try to reduce it a lot.

#### Let's adjust the machine so that 1000g is:

- at -3 standard deviations:
  - a. From the big bell curve above we see that 0.1% are less. But maybe that is too small.

- at -2.5 standard deviations:
  - a. Below 3 is 0.1% and between 3 and 2.5 standard deviations is 0.5%, together that is 0.1% + 0.5% = 0.6% (a good choice I think)

So let us adjust the machine to have 1000g at −2.5 standard de mean.	viations from the

Now, we can adjust it to:

• increase the amount of sugar in each bag (which changes the mean), or

make it more accurate (which reduces the standard deviation)

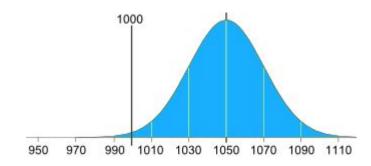

Let us try both.

#### **A**DJUST THE MEAN AMOUNT IN EACH BAG

The standard deviation is 20g, and we need 2.5 of them:

$$2.5 \times 20g = 50g$$

So the machine should average 1050g, like this:

### Adjust the accuracy of the machine

Or we can keep the same mean (of 1010g), but then we need 2.5 standard deviations to be equal to 10g:

$$10g / 2.5 = 4g$$

950 970 990 1010 1030 1050 1070

So the standard deviation should be 4q, like this:

(We hope the machine is that accurate!)

Or perhaps we could have some combination of better accuracy and slightly larger average size, I will leave that up to you!
